Jeppesen, PhD; Dario Rahelić, MD, PhD; Hana Kahleová, MD, PhD; Jordi Salas-Salvadó, MD, PhD; Cyril W. C. Kendall, PhD; John L. Sievenpiper, MD, PhD

Abstract

IMPORTANCE There are concerns that low- and no-calorie sweetened beverages (LNCSBs) do not have established benefits, with major dietary guidelines recommending the use of water and not LNCSBs to replace sugar-sweetened beverages (SSBs). Whether LNCSB as a substitute can yield similar improvements in cardiometabolic risk factors vs water in their intended substitution for SSBs is unclear.

OBJECTIVE To assess the association of LNCSBs (using 3 prespecified substitutions of LNCSBs for SSBs, water for SSBs, and LNCSBs for water) with body weight and cardiometabolic risk factors in adults with and without diabetes.

DATA SOURCES Medline, Embase, and the Cochrane Central Register of Controlled Trials were searched from inception through December 26, 2021.

STUDY SELECTION Randomized clinical trials (RCTs) with at least 2 weeks of interventions comparing LNCSBs, SSBs, and/or water were included.

DATA EXTRACTION AND SYNTHESIS Data were extracted and risk of bias was assessed by 2 independent reviewers. A network meta-analysis was performed with data expressed as mean difference (MD) or standardized mean difference (SMD) with 95% CIs. The GRADE (Grading of Recommendations Assessment, Development and Evaluation) system was used to assess the certainty of the evidence.

MAIN OUTCOMES AND MEASURES The primary outcome was body weight. Secondary outcomes were other measures of adiposity, glycemic control, blood lipids, blood pressure, measures of nonalcoholic fatty liver disease, and uric acid.

RESULTS A total of 17 RCTs with 24 trial comparisons were included, involving 1733 adults (mean [SD] age, 33.1 [6.6] years; 1341 women [77.4%]) with overweight or obesity who were at risk for or had diabetes. Overall, LNCSBs were a substitute for SSBs in 12 RCTs (n = 601 participants), water was a substitute for SSBs in 3 RCTs (n = 429), and LNCSBs were a substitute for water in 9 RCTs (n = 974). Substitution of LNCSBs for SSBs was associated with reduced body weight (MD, -1.06 kg; 95% CI, -1.71 to -0.41 kg), body mass index (MD, -0.32; 95% CI, -0.58 to -0.07), percentage of body fat (MD, -0.60%; 95% CI, -1.03% to -0.18%), and intrahepatocellular lipid (SMD, -0.42; 95% CI, -0.70 to -0.14). Substituting water for SSBs was not associated with any outcome. There was also no association found between substituting LNCSBs for water with any outcome except glycated

(continued)

Key Points

Question Are low- and no-calorie sweetened beverages (LNCSBs) as the intended substitute for sugar-sweetened beverages (SSBs) associated with improved body weight and cardiometabolic risk factors similar to water replacement?

Findings In this systematic review and meta-analysis of 17 randomized clinical trials, LNCSBs as a substitute for SSBs were associated with reduced body weight, body mass index, percentage of body fat, and intrahepatocellular lipid, providing benefits that were similar to those of water, the standard-of-care substitution.

Meaning The findings of this study suggest that over the moderate term, LNCSBs are a viable alternative to water as a replacement strategy in adults with overweight or obesity who are at risk for or have diabetes.

Abstract (continued)

hemoglobin A_{1c} (MD, 0.21%; 95% CI, 0.02% to 0.40%) and systolic blood pressure (MD, -2.63 mm Hg; 95% CI, -4.71 to -0.55 mm Hg). The certainty of the evidence was moderate (substitution of LNCSBs for SSBs) and low (substitutions of water for SSBs and LNCSBs for water) for body weight and was generally moderate for all other outcomes across all substitutions.

CONCLUSIONS AND RELEVANCE This systematic review and meta-analysis found that using LNCSBs as an intended substitute for SSBs was associated with small improvements in body weight and cardiometabolic risk factors without evidence of harm and had a similar direction of benefit as water substitution. The evidence supports the use of LNCSBs as an alternative replacement strategy for SSBs over the moderate term in adults with overweight or obesity who are at risk for or have diabetes.

JAMA Network Open. 2022;5(3):e222092. doi:10.1001/jamanetworkopen.2022.2092

Introduction

Sugar consumption has emerged as an important public health concern. The evidence on this concern derives largely from consumption of sugar-sweetened beverages (SSBs), with excess intake of SSBs associated with weight gain and downstream cardiometabolic complications.¹⁻⁴ Sugar-sweetened beverages have been identified as an important public health target.^{5,6} It is unclear whether low- and no-calorie sweetened beverages (LNCSBs) as a replacement strategy for SSBs provide the intended benefits. Recent systematic reviews and meta-analyses⁷ have shown an association between LNCSBs and a higher risk of the conditions that they are intended to prevent, such as weight gain, diabetes, and cardiovascular disease, in prospective cohort studies⁸ and have reported inconsistent findings for weight loss and improvements in downstream cardiometabolic risk factors in randomized clinical trials (RCTs).^{7,8} Biological mechanisms involving impaired sensory and endocrine signaling that was mediated by the sweet taste receptor^{9,10} and changes to the microbiome^{10,11} have been implicated in support of these observations.

Methodological considerations, however, have been raised that limit the inferences that can be drawn from these data. The available prospective cohort studies are at high risk for reverse causality.¹²⁻¹⁴ Furthermore, the syntheses of RCTs do not fully account for the calories available to be displaced by LNCSBs, with caloric (eg, SSBs) and noncaloric (eg, water and placebo) comparators that are pooled together or with noncaloric comparators that are used as the sole comparator, leading to an underestimation of the outcome of LNCSBs.¹²⁻¹⁴

The prevailing uncertainties have led to mixed recommendations from authoritative bodies. Neither the Dietary Guidelines for Americans nor Canada's Food Guide supports the use of LNCSBs, and instead both recommend replacing SSBs with water.^{5,6} The American Heart Association supports a narrow indication for LNCSBs, recommending that LNCSBs should be used as a replacement by only adults who are habitual consumers of SSBs, but emphasizing the use of water or an unsweetened alternative.¹⁵ Similarly, diabetes associations in the UK, US, and Canada support LNCSBs insofar as they are used to displace calories from sugars and SSBs.¹⁶⁻¹⁸ The European Association for the Study of Diabetes has not made any specific recommendations about low- and no-calorie sweeteners (LNCSs) or LNCSBs.¹⁹ To update the recommendations of the European Association for the Study of Diabetes, the Diabetes and Nutrition Study Group commissioned the present systematic review and meta-analysis to summarize the evidence from RCTs of the association of LNCSBs, the most important source of LNCSs in a diet and a single food matrix, with intermediate cardiometabolic outcomes.²⁰ Because of the importance of the comparator in drawing inferences about LNCSBs, we conducted network meta-analyses rather than traditional pairwise meta-analyses to assess the association of LNCSBs with body weight and cardiometabolic risk factors in adults with and without diabetes. We used 3 prespecified substitutions: LNCSBs for SSBs

(intended substitution with caloric displacement), water for SSBs (standard-of-care substitution with caloric displacement), and LNCSBs for water (reference substitution without caloric displacement).

Methods

This systematic review and network meta-analysis was conducted according to the *Cochrane Handbook for Systematic Reviews of Interventions*²¹ and the Preferred Reporting Items for Systematic Reviews and Meta-analyses (PRISMA) reporting guideline.²² The protocol is registered at ClinicalTrials.gov (NCT02879500).

Data Sources, Searches, and Study Selection

We searched Medline, Embase, and the Cochrane Central Register of Controlled Trials from inception through December 26, 2021. Briefly, for this search, we used variations of the exposure terms (LNCSBs and SSBs), outcome terms (adiposity, glycemia, blood lipids, blood pressure [BP], nonalcoholic fatty liver disease [NAFLD], and uric acid), and study design terms (randomized controlled trial, randomized, and placebo). The full search strategy is presented in eTables 1 to 3 in the [Supplement](#). Manual searches of the reference lists of included studies and reviews were also performed.

eTable 4 in the [Supplement](#) shows the PICOTS (Population, Intervention, Comparator, Outcome, Time, and Study) framework.²² We included RCTs of at least 2 weeks that investigated the association of LNCSBs, SSBs, and/or water with cardiometabolic risk factors. We excluded trials that had multimodal interventions, did not use comparator groups containing at least 1 of the other beverage interventions, included children and pregnant or breastfeeding women, or did not provide viable outcome data. Trials of LNCSBs in fortified or nutrient-dense beverages (eg, milk and juice) were also excluded because of the presence of other nutrients.

Data Extraction, Risk of Bias Assessment, and Outcomes

Two independent reviewers (N.D.M. and R.Z.) extracted relevant data from each included report (eMethods in the [Supplement](#)). Additional information was requested from study authors when necessary. Race and ethnicity data were not collected because the available data were not presented by these variables.

The same independent reviewers (N.D.M. and R.Z.) assessed risk of bias for each included RCT using the Cochrane risk-of-bias tool.²³ Five domains of bias were assessed: sequence generation, allocation concealment, blinding of participants and personnel, incomplete outcome data, and selective reporting. Disagreements between the reviewers were resolved by consensus.

The primary outcome was body weight. Secondary outcomes were other measures of adiposity (body mass index [BMI], which was calculated as weight in kilograms divided by height in meters squared; percentage of body fat; and waist circumference), glycemic control (glycated hemoglobin A_{1c} [HbA_{1c}], fasting plasma glucose, 2-hour postprandial glucose during a 75-g oral glucose tolerance test, fasting plasma insulin [FPI], and homeostatic model assessment of insulin resistance), blood lipids (low-density lipoprotein cholesterol, non-high-density lipoprotein cholesterol, triglycerides, high-density lipoprotein cholesterol, and total cholesterol), BP (systolic BP and diastolic BP), measures of NAFLD (intrahepatocellular lipid [IHCL], alanine aminotransferase, and aspartate aminotransferase), and uric acid. Change differences were preferred over end differences. Missing variance data were calculated using established formulas.²¹

Data Synthesis and Grading the Evidence

This network meta-analysis was based on a frequentist framework and was conducted using the network suite of commands in Stata, version 15 (StataCorp LLC). We used change from baseline values from each study to calculate the mean differences (MDs) between treatments for each substitution (LNCSBs for SSBs, water for SSBs, and LNCSBs for water); otherwise, we used

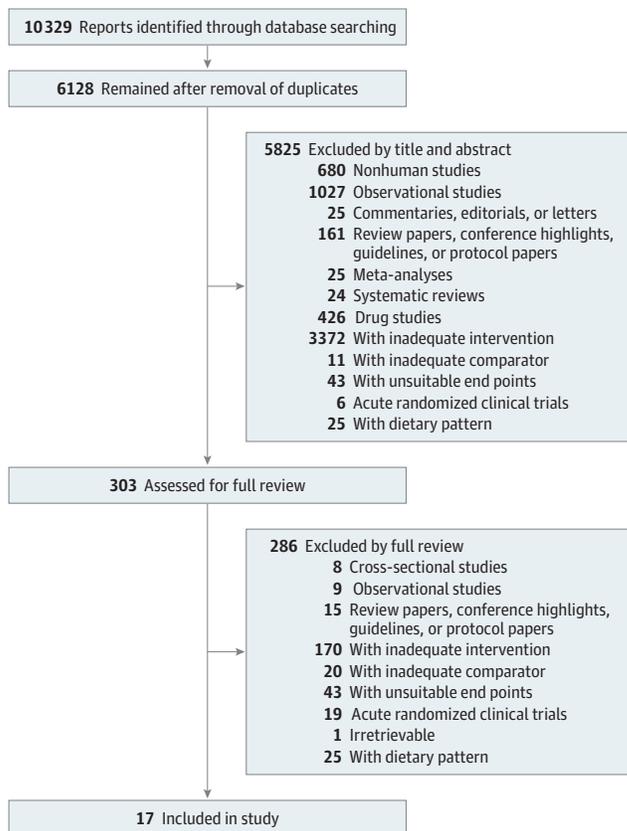

postintervention values (eMethods and eData 1-20 in the Supplement). We performed random-effects network meta-analyses for each outcome to compare the 3 interventions (LNCSBs, SSBs, and water) simultaneously. Inconsistency was assessed in the direct, indirect, and network estimates. We assessed interstudy heterogeneity in the direct (pairwise) estimates using the Cochran Q statistic with quantification by the I^2 statistic, where $I^2 \geq 50\%$ and $P < .10$ were considered to be substantial interstudy heterogeneity. We measured incoherence in the network estimates using both local (loop-specific and side-splitting) and global (design-by-treatment interaction model) approaches.²⁴⁻²⁶ If 10 or more trials were available, we conducted a priori subgroup analyses by age, study duration, type of design, disease status, risk of bias, and funding source. Indirectness was assessed in the indirect comparisons by evaluation of intransitivity across the pairwise comparisons comprising the indirect estimates for the study characteristics of age, study length, sample size, and percentage of male participants. Publication bias was assessed if 10 or more trial comparisons were available; we used comparison-adjusted funnel plots to assess funnel plot asymmetry.²⁴

We assessed the certainty of the evidence using the Grading of Recommendations Assessment, Development and Evaluation (GRADE) system.^{20,27-30} Network estimates of RCTs and the direct and indirect estimates that composed these network estimates started at a high certainty of evidence but were downgraded by established criteria for risk of bias, inconsistency (incoherence), indirectness, imprecision, and publication bias (eMethods in the Supplement).

Results

Figure 1 shows the flow of the literature search and selection, and eFigures 27 to 46 in the Supplement show the network diagram for each outcome. We identified 4541 reports, of which 13

Figure 1. Literature Search for Randomized Clinical Trials of Low- and No-Calorie Sweetened Beverages

met the eligibility criteria. An additional 4 reports were found through manual searching. A total of 17 RCTs with 24 trial comparisons were included that assessed the association of the 3 prespecified substitutions with body weight, other measures of adiposity, and cardiometabolic risk.³¹⁻⁴⁷ These RCTs involved 1733 adult participants (mean [SD] age, 33.1 [6.6] years; 1341 women [77.4%] and 392 men [22.6%]) with overweight or obesity who were at risk for or had diabetes.

The **Table** and eTable 5 in the **Supplement** provide key trial characteristics.³¹⁻⁴⁷ Overall, the RCTs had a medium sample size, with a median (range) number of 72 (27-308) participants, and involved more women than men (23% men to 77% women). Most participants were younger (median [range] age, 34 [23-48] years) and had overweight or obesity (median [range] BMI, 31 [22-36]), with 9 trials^{31-36,38-42,44-46} that included only participants with overweight and/or obesity and 1 trial⁴⁰ that included participants with type 2 diabetes.

Only 8 trials (11 comparisons)^{31,32,35,37,38,43-45,47} reported the type of LNCS used in the LNCSBs: 7 comparisons for aspartame and 1 comparison each for aspartame and acesulfame potassium blend, saccharin, rebaudioside A, and sucralose. Overall, LNCSBs were a substitute for SSBs in 12 trials (n = 601 participants),^{33-35,38,43-45,47} water was a substitute for SSBs in 3 trials (n = 429),^{33,35,36,41} and LNCSBs were a substitute for water in 9 trials (n = 974).^{31,33,35,37,39,40,42,46} The median (range) dosages were 1000 (250-2000) mL per day for LNCSBs, 1000 (250-1750) mL per day for SSBs, and 580 (250- 2000) mL per day for water.

Fifteen trials³²⁻⁴⁶ had a parallel design, and 2 trials^{31,47} had a crossover design. Most RCTs were conducted in Europe (n = 8) and North America (n = 6). The median (range) duration of follow-up was 12 (3-52) weeks. Eight trials^{33,34,38-40,43,44,47} were funded by agencies (government, not-for-profit health agency, or university sources), 4 trials^{36,37,42,46} were funded by industry, and 5 trials^{31,32,35,41,45} were funded by a combination of agency and industry. We contacted the authors of 7 studies^{31,32,34,35,38,44,45} for additional data, and the authors of 2 studies^{34,38} provided additional data.

eFigures 1 and 2 in the **Supplement** provide the Cochrane risk-of-bias tool assessments. Eight trial comparisons^{32,34,35,37,41,43,44,47} received an unclear risk-of-bias rating, and 11 comparisons^{31,33,36,38-40,42,46} were rated as having a low risk of bias. No RCTs were identified as having a high risk of bias, with no evidence of serious summary risk of bias across the trials.

Associations of the Prespecified Substitutions

Figure 2 shows the network meta-analyses of the association of the intended substitution of LNCSBs for SSBs with body weight, other measures of adiposity, and cardiometabolic risk factors. This substitution was associated with reduced body weight (MD, -1.06 kg; 95% CI, -1.71 to -0.41 kg) and lower BMI (MD, -0.32; 95% CI, -0.58 to -0.07), percentage of body fat (MD, -0.60%; 95% CI, -1.03% to -0.18%), and IHCL (standardized MD [SMD], -0.42; 95% CI, -0.70 to -0.14). No other outcomes had significant differences.

Figure 3 shows the network meta-analyses of the association of the standard-of-care substitution of water for SSBs with body weight, other measures of adiposity, and cardiometabolic risk factors. Neither the primary outcome of body weight (MD, -0.01 kg; 95% CI, -0.95 to 0.98 kg) nor any of the secondary outcomes showed significant differences, although the direction of association favored water for most of the outcomes.

Figure 4 shows the network analyses of the association of the reference substitution of LNCSBs for water with body weight, other measures of adiposity, and cardiometabolic risk factors. Greater reduction in body weight (MD, -1.07 kg; 95% CI, -1.95 to -0.19 kg) was associated with LNCSBs compared with water. Among secondary outcomes, water compared with LNCSBs was associated with lower level of HbA_{1c} (MD, 0.21%; 95% CI, 0.02% to 0.40%), and LNCSBs compared with water were associated with a greater decrease in systolic BP (MD, -2.63 mm Hg; 95% CI, -4.71 to -0.55 mm Hg). No secondary outcomes were affected.

Table. Trial Characteristics

Source and country	Total No. of participants	Population	Age, mean (SD), y	No. of participants by sex (%)	LNCS type	Beverage dosage, mL/d			Design	Duration, wk	Funding source
						LNCSB	Water	SSB

Abbreviations: LNCS, low- and no-calorie sweetener; LNCSB, low- and no-calorie sweetened beverage; NA, not applicable; NR, not reported; SSB, sugar-sweetened beverage.

^a Secondary analyses to Maersk et al.⁴¹ As more outcomes were reported in the Engel et al³⁵ analysis, data from that trial were used for most outcomes, except for uric acid (Bruun et al³²) and intrahepatocellular lipid (Maersk et al⁴¹).

Adverse Events and Inconsistency

Adverse events were reported in 4 trials,^{33,36,43,44} including tiredness, mood swings, headaches, body aches, nausea, hospitalizations, and weight gain. In all cases, the adverse events were not observed,^{43,44} deemed to be unrelated to the intervention,³³ or not severe enough to be of consequence.³⁶

eTables 6 and 7 in the Supplement show the loop-specific and the design-by-treatment assessment of inconsistency (incoherence) in the network estimates. No significant incoherence was observed by any approach across the 3 substitutions.

eFigures 7 to 26 in the Supplement provide the assessments of network, direct and indirect estimates, inconsistency (heterogeneity) in the direct estimates, and inconsistency (incoherence) between the direct and indirect estimates using side-splitting method. There was evidence of substantial heterogeneity ($I^2 \geq 50\%$; $P < .10$) in the direct pairwise estimates of the association of LNCSBs as a substitute for water with the primary outcome of body weight and secondary outcomes of waist circumference, HbA_{1c}, FPI, homeostatic model assessment of insulin resistance, and triglycerides. Incoherence was not significant for any comparison, but on visual inspection slight instability between direct and indirect measures was present for BMI, percentage of body fat, HbA_{1c}, fasting blood glucose, FPI, homeostatic model assessment of insulin resistance, low-density lipoprotein cholesterol, triglycerides, high-density lipoprotein cholesterol, total cholesterol, systolic BP, diastolic BP, IHCL, alanine aminotransferase, aspartate aminotransferase, and uric acid.

Subgroup Analyses, Intransitivity, and Publication Bias

Because no outcome had 10 or more trials in all 3 comparisons, we did not conduct subgroup analyses.

eFigures 3 to 6 in the Supplement present the evaluation of intransitivity (a domain of indirectness) among the indirect comparisons by comparing the distribution of the potential effect modifiers across the available direct comparisons for age, study length, sample size, and percentage of males. The assumption of transitivity was met for all indirect comparisons as there was no overlap in the range between the pairwise comparisons.

eFigures 47 to 57 in the Supplement show the comparison-adjusted funnel plots for outcomes with 10 or more trial comparisons (body weight, BMI, percentage of body fat, FPI, fasting plasma glucose, low-density lipoprotein cholesterol, high-density lipoprotein cholesterol, triglycerides, total cholesterol, and systolic BP). Funnel plot asymmetry was not observed for any of the outcomes.

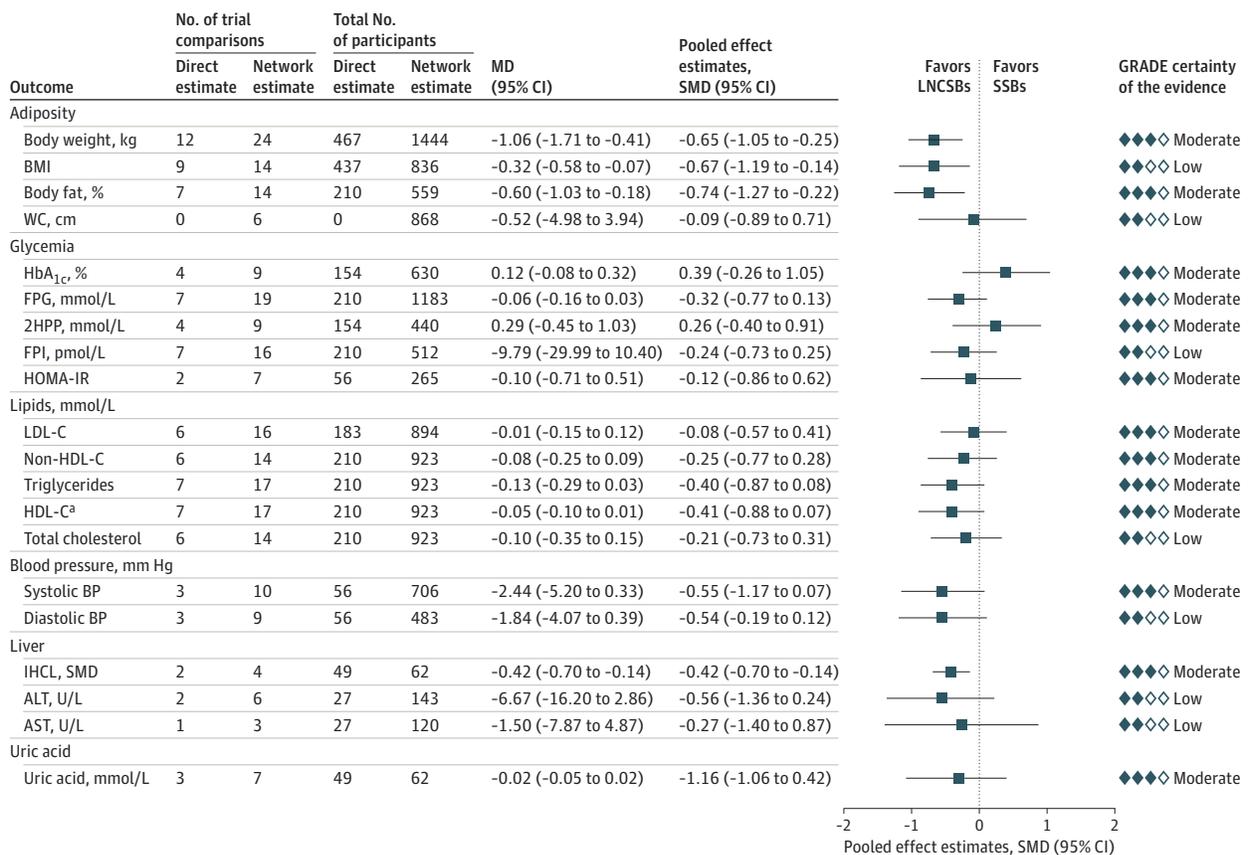

GRADE Assessment

eFigures 7 to 26 in the Supplement include the GRADE assessment for the network meta-analysis. The certainty of the evidence for body weight was moderate for LNCSBs as a substitute for SSBs (small reduction; downgrade for imprecision), moderate for water as a substitute for SSBs (no difference; downgrades for inconsistency and imprecision), and low for LNCSBs as a substitute for water (small reduction; downgrades for inconsistency and imprecision). The certainty of the evidence for the adiposity and cardiometabolic outcomes was generally moderate, ranging from very low to high for each of the 3 substitutions (downgrades for inconsistency, imprecision, and/or indirectness) and with nearly all directions of the association favoring the use of LNCSBs or water as a substitute for SSBs (small to trivial reductions) and diverging for the use of LNCSBs as a substitute for water (small to no differences).

Discussion

In the present systematic review and meta-analysis, the use of LNCSBs as a substitute for SSBs was associated with reduced body weight, BMI, percentage of body fat, and IHCL, whereas the use of

Figure 2. Substitution of Low- and No-Calorie Sweetened Beverages (LNCSBs) for Sugar-Sweetened Beverages (SSBs)

Data were pooled using network random-effects models and expressed as mean differences (MDs) and 95% CIs. To display the results for outcomes on the same plot, standardized mean differences (SMDs, represented by blue squares) and pseudo 95% CIs (represented by black horizontal lines and proportionally scaled to the 95% CIs of the MDs) were calculated. 2HPP indicates 2-hour postprandial glucose; ALT, alanine aminotransferase (to convert to $\mu\text{kat/L}$, multiply by 0.0167); AST, aspartate aminotransferase (to convert to $\mu\text{kat/L}$, multiply by 0.0167); BMI, body mass index; FPG, fasting plasma glucose; FPI, fasting plasma insulin; GRADE, Grading of

Recommendations Assessment, Development and Evaluation; HbA_{1c}, glycated hemoglobin A_{1c}; HDL-C, high-density lipoprotein cholesterol; HOMA-IR, homeostatic model assessment of insulin resistance; IHCL, intrahepato cellular lipid; LDL-C, low-density lipoprotein cholesterol; and WC, waist circumference.

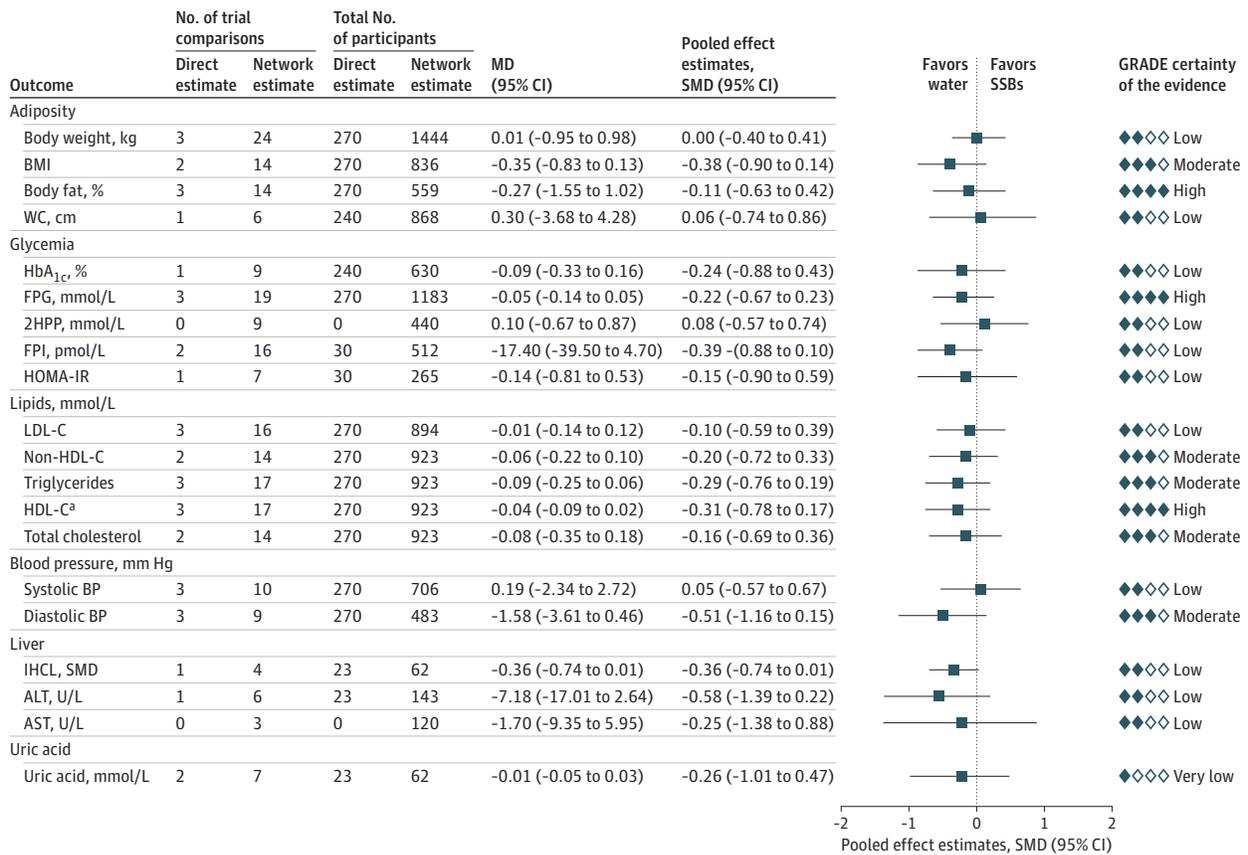

^a HDL-C result has been reversed for display purposes; that is, a negative MD would mean a positive improvement.

water as a substitute for SSBs was associated with no significant improvements, although the direction of association favored water in all cases. Furthermore, neither LNCSBs nor water as a substitute for SSBs was associated with significant improvements in glycemic control, BP, uric acid, or other aspects of the lipid profile or NAFLD markers, but the directions of the association favored LNCSBs or water in nearly all cases. The use of LNCSBs as a substitute for water did not show significant differences, except for a greater decrease in HbA_{1c} seen with water and in body weight and systolic BP seen with LNCSBs.

Findings in the Context of Existing Studies

The findings in this study are in agreement with those reported in other systematic reviews and meta-analyses,⁴⁸⁻⁵¹ which have allowed for the interpretation of results by comparator. Specifically, the findings that (1) reduced body weight, BMI, and body fat were associated with the use LNCSBs as a substitute for SSBs with caloric displacement and (2) neutral outcomes were associated with the use of LNCSBs as a substitute for water without caloric displacement are consistent with the results of other systematic reviews and meta-analyses of RCTs.⁴⁸⁻⁵¹

Figure 3. Substitution of Water for Sugar-Sweetened Beverages (SSBs)

Data were pooled using network random-effects models and expressed as mean differences (MDs) and 95% CIs. To display the results for outcomes on the same plot, standardized mean differences (SMDs, represented by blue squares) and pseudo 95% CIs (represented by black horizontal lines and proportionally scaled to the 95% CIs of the MDs) were calculated. 2HPP indicates 2-hour postprandial glucose; ALT, alanine aminotransferase (to convert to $\mu\text{kat/L}$, multiply by 0.0167); AST, aspartate aminotransferase (to convert to $\mu\text{kat/L}$, multiply by 0.0167); BMI, body mass index; FPG, fasting plasma glucose; FPI, fasting plasma insulin; GRADE, Grading of

^a HDL-C result has been reversed for display purposes; that is, a negative MD would mean a positive improvement.

Decreases in body weight,^{48,49} body weight and BMI,⁵⁰ and a composite of body weight or BMI⁵¹ were observed with the substitution of LNCSs for a caloric comparator (sugars in foods or beverages) predominantly in participants with overweight or obesity. Miller and Perez⁵⁰ further showed reductions in fat mass and waist circumference. Similarly, Toews et al⁷ found small reductions in BMI with sucrose in foods or beverages as the caloric comparator in predominantly healthy participants. On the other hand, undifferentiated analyses by Toews et al⁷ of the outcome of substituting LNCSs for a combination of caloric and noncaloric comparators and another analysis by Azad et al⁸ that restricted the outcome of substituting LNCSBs for matched noncaloric comparators (placebo, water, or weight loss diet) found no differences in body weight with LNCSs predominantly in participants with overweight or obesity. Overall, these findings are consistent with the mechanism of LNCSBs being associated with weight loss insofar as they were a factor in reducing net energy intake.

The observed improvements in downstream, intermediate cardiometabolic outcomes are also in agreement with findings of previous systematic reviews and meta-analyses. In addition to their association with weight gain,⁵² fructose-containing sugars that provide excess calories, especially in beverage form, have been associated with increased triglycerides,^{53,54} glucose,⁵⁵ insulin,⁵⁵ uric

Figure 4. Substitution of Low- and No-Calorie Sweetened Beverages (LNCSBs) for Water

Data were pooled using network random-effects models and expressed as mean differences (MDs) and 95% CIs. To display the results for outcomes on the same plot, standardized mean differences (SMDs, represented by blue squares) and pseudo 95% CIs (represented by black horizontal lines and proportionally scaled to the 95% CIs of the MDs) were calculated. 2HPP indicates 2-hour postprandial glucose; ALT, alanine aminotransferase (to convert to $\mu\text{kat/L}$, multiply by 0.0167); AST, aspartate aminotransferase (to convert to $\mu\text{kat/L}$, multiply by 0.0167); BMI, body mass index; FPG, fasting plasma glucose; FPI, fasting plasma insulin; GRADE, Grading of

Recommendations Assessment, Development and Evaluation; HbA_{1c}, glycated hemoglobin A_{1c}; HDL-C, high-density lipoprotein cholesterol; HOMA-IR, homeostatic model assessment of insulin resistance; IHCL, intrahepato cellular lipid; LDL-C, low-density lipoprotein cholesterol; and WC, waist circumference.

^a HDL-C result has been reversed for display purposes; that is, a negative MD would mean a positive improvement.

acid,⁵⁶ and NAFLD markers.⁵⁷ Toews et al⁷ showed that the use of LNCSs as a substitute for caloric sugars (sucrose) were a factor in reduced BP, and the reductions seen in IHCL would be expected through displacement of calories from SSBs.

The findings of this study can inform guidance on the role of LNCSBs in sugar-reduction strategies. There has been a particular focus on SSBs as the most important source of added or free sugars in several countries,⁵⁸⁻⁶⁰ given that the overconsumption of sugar has been associated with weight gain, diabetes, and downstream complications of hypertension and coronary heart disease.¹⁻⁴ Although water is considered to be the standard-of-care substitution for SSBs by authoritative bodies,^{5,6,15-19} with many health organizations recommending against the use of LNCSBs, the existing evidence confirms the intended benefits of LNCSBs as a substitute for SSBs over the moderate term. For habitual consumers of SSBs with overweight or obesity, who are at risk for or have type 2 diabetes, and who are unable to switch to water, LNCSBs may provide a viable alternative. This finding is particularly important given that most people in the National Weight Control Registry who are successful at weight loss maintenance consume LNCSBs and report that LNCSBs help in controlling caloric intake and weight loss maintenance.⁶¹

There is a need for high-quality RCTs that focus on quantifying the outcome of LNCSBs using different LNCS blends as substitutes for SSBs compared with the outcome of water (the standard-of-care substitution). We await the results of the STOP Sugars NOW (Strategies to Oppose Sugars With Non-nutritive Sweeteners or Water) trial and other similar RCTs to help clarify the role of LNCSBs. Future research using a range of designs is warranted to confirm whether the intended benefits of using LNCSBs as a substitute for SSBs are durable and extend to hard clinical outcomes.

Strengths and Limitations

This systematic review and meta-analysis has several strengths. First, the use of network meta-analysis allowed for the simultaneous assessment of the 3 prespecified substitutions (LNCSBs for SSBs, water for SSBs, and LNCSBs for water), leveraging direct and indirect comparisons with a common comparator to increase the information size. Undertaking a network meta-analysis rather than a regular pairwise meta-analysis provided 2 distinct advantages: (1) more precise estimates than single direct or indirect estimates, and (2) the ability to compare interventions that had not been compared before. Second, a comprehensive literature search that included only RCTs provided the greatest protection against bias, no evidence of serious risk of bias among the included trials, and use of the GRADE approach to assess the certainty of the estimates.

This systematic review and meta-analysis also has several limitations. First, evidence of inconsistency was present in the primary outcome of body weight across the substitutions of water for SSBs and LNCSBs for water and in several secondary outcomes across the 3 prespecified substitutions, resulting in downgrades for serious inconsistency. This inconsistency was associated with either unexplained heterogeneity in the direct estimates or incoherence from the difference between direct and indirect estimates. Network estimates closely followed the direct estimate, with indirect estimates improving precision when coherent and only trivially affecting network estimates when incoherent. Second, there was evidence of serious indirectness in several of the analyses. Only 1 RCT of direct comparisons was available for several secondary outcomes, limiting generalizability and leading to downgrades for serious indirectness. The moderate median follow-up duration of 12 weeks was considered to be another potential source of indirectness across the analyses. Although there is some uncertainty about whether the benefits and lack of harm associated with LNCSBs extended beyond the 12-week median follow-up, any harm may have manifested within this time frame. The analyses also included RCTs with up to 1 year of follow-up that showed no evidence of harm or even benefit.^{33,42} Other large RCTs in children and adolescents (which were not captured in the present analyses) offer further evidence of durable benefit.^{62,63} Therefore, we did not downgrade the evidence for the lack of long-term follow-up as a source of indirectness and instead made all conclusions specific to the moderate term. Third, there was evidence of serious imprecision in several of the pooled estimates. The 95% CIs crossed the prespecified minimal important

differences for the primary outcome of body weight and several secondary outcomes across the 3 prespecified substitutions. Balancing the strengths and limitations, we assessed the certainty of the evidence as generally low to moderate for most outcomes.

Conclusions

In this systematic review and meta-analysis, using LNCSBs as an intended substitute for SSBs appeared to be associated with reductions in body weight and cardiometabolic risk factors, including BMI, percentage of body fat, and IHCL, without evidence of harm. These small improvements were similar in direction to those associated with water substitution, the standard of care. The evidence provides a good indication of the benefits of LNCSBs as an alternative replacement strategy over the moderate term for SSBs in adults with overweight or obesity who are at risk for or have diabetes.

Administrative, technical, or material support: McGlynn, Khan, Lee, Blanco Mejia, Hill, Agarwal, Rahelić.

Supervision: Khan, Jeppesen, Kendall, Sievenpiper.

Conflict of Interest Disclosures: Ms McGlynn reported receiving a Canadian Institutes of Health Research (CIHR)-Masters Award during the conduct of the study and being a former employee of Loblaw's Companies Limited outside the submitted work. Dr Khan reported receiving grants from CIHR, International Life Science Institute, and National Honey Board outside the submitted work. Dr Chiavaroli reported being a Mitacs Elevate postdoctoral fellow and receiving joint funding from the Government of Canada and the Canadian Sugar Institute. Mr Au-Yeung reported receiving personal fees from Inquis Clinical Research outside the submitted work. Ms Lee reported receiving graduate scholarship from CIHR and the Banting & Best Diabetes Centre at the University of Toronto outside the submitted work. Dr Comelli reported being the Lawson Family Chair in Microbiome Nutrition Research at the Joannah and Brian Lawson Centre for Child Nutrition, University of Toronto, during the conduct of the study and receiving nonfinancial support from Lallemand Health Solutions, donation to research program from Lallemand Health Solutions, personal fees from Danone, sponsored research and collaboration agreement from Ocean Spray, and nonfinancial support from Ocean Spray outside the submitted work. Ms Ahmed reported receiving scholarship from the Toronto Diet, Digestive tract, and Disease Centre (3D) outside the submitted work. Dr Malik reported receiving personal fees from the City and County of San Francisco, Kaplan Fox & Kilsheimer LLP, and World Health Organization outside the submitted work and support from the Canada Research Chairs Program. Dr Hill reported receiving personal fees from General Mills and McCormick Science Institute. Dr Rahelić reported receiving personal fees from the International Sweeteners Association, Abbott, AstraZeneca, Boehringer Ingelheim, Eli Lilly, Novo Nordisk, Merck, MSD, Salvus, and Sanofi outside the submitted work. Dr Salas-Salvadó reported receiving personal fees from Instituto Danone Spain, nonfinancial support from Danone Institute International, personal fees as director of the World Forum for Nutrition Research and Dissemination from the International Nut and Dried Fruit Council Foundation, financial support to the institution from Fundación Eroski, and financial support to the institution from Danone outside the submitted work. Dr Kendall reported receiving grants and/or in-kind support from Advanced Food Materials Network, Agriculture and Agri-Food Canada, CIHR, Almond Board of California, Barilla, Canola Council of Canada, International Nut and Dried Fruit Council, Peanut Institute, Pulse Canada, Tate and Lyle Nutritional Research Fund at the University of Toronto, and Unilever; receiving nonfinancial support from General Mills, Kellogg, Loblaw Brands Limited, Oldways Preservation Trust, Quaker Oats (Pepsi-Co), Sun-Maid, White Wave Foods/Danone, International Pasta Organization, California Walnut Commission, Primo, Unico, International Carbohydrate Quality Consortium (ICQC), and Toronto Diet, Digestive tract, and Disease Centre (3D) outside the submitted work; receiving personal fees from McCormick Science Institute and Lantmannen; and being a member of the Diabetes and Nutrition Study Group (DNSG) Executive Board and Dietary Guidelines, a member of the expert committee of the DNSG Clinical Practice Guidelines for Nutrition Therapy, a member of the scientific advisory board of the McCormick Science Institute, a scientific advisor for the International Pasta Organization and Oldways Preservation Trust, a member of the ICQC, an executive board member of the DNSG, and being the director of the Toronto Diet, Digestive tract, and Disease Centre (3D) Knowledge Synthesis and Clinical Trials Foundation. Dr Sievenpiper reported receiving nonfinancial support from DNSG of the European Association for the Study of Diabetes (EASD), grants from CIHR through the Canada-wide Human Nutrition Trialists' Network (NTN), PSI Graham Farquharson Knowledge Translation Fellowship, Diabetes Canada Clinician Scientist Award, CIHR Institute of Nutrition, Metabolism and Diabetes and the Canadian Nutrition Society (INMD/CNS) New Investigator Partnership Prize, and Banting & Best Diabetes Centre Sun Life Financial New Investigator Award during the conduct of the study; receiving grants from American Society for Nutrition, International Nut and Dried Fruit Council Foundation, National Honey Board (the US Department of Agriculture [USDA] honey checkoff program), Institute for the Advancement of Food and Nutrition Sciences (IAFNS; formerly ILSI North America), Pulse Canada, Quaker Oats Center of Excellence, United Soybean Board (the USDA soy checkoff program), Tate and Lyle Nutritional Research Fund at the University of Toronto, Glycemic Control and Cardiovascular Disease in Type 2 Diabetes Fund at the University of Toronto (a fund established by the Alberta Pulse Growers), and Nutrition Trialists Fund at the University of Toronto (a fund established by an inaugural donation from the Calorie Control Council); receiving personal fees from Dairy Farmers of Canada, FoodMinds LLC, International Sweeteners Association, Nestlé, Abbott, General Mills, American Society for Nutrition, INC Nutrition Research and Education Foundation, European Food Safety Authority, Nutrition Communications, International Food Information Council, Calorie Control Council, Comité Européen des Fabricants de Sucre, International Glutamate Technical Committee, Perkins Coie LLP, Tate and Lyle Nutritional Research Fund at the University of Toronto, Danone, Inquis Clinical Research, Soy Nutrition Institute, and European Fruit Juice Association outside the submitted work; serving on the clinical practice guidelines expert committees of Diabetes Canada, EASD, Canadian Cardiovascular Society, and Obesity Canada/Canadian Association of Bariatric Physicians and Surgeons; being an unpaid scientific advisor for the Food, Nutrition, and Safety Program and the Technical Committee on Carbohydrates of IAFNS; being a member of the ICQC, executive board member of the

DNSG of the EASD, and director of the Toronto Diet, Digestive tract, and Disease Centre (3D) Knowledge Synthesis and Clinical Trials Foundation; his spouse is an employee of AB InBev. No other disclosures were reported.

Funding/Support: This study was commissioned by the DNSG of the EASD, which provided funding and logistical support for meetings as part of the development of the EASD Clinical Practice Guidelines for Nutrition Therapy. This study was also supported by grant 129920 from CIHR through the Canada-wide NTN. The Toronto Diet, Digestive tract, and Disease Centre (3D), funded through the Canada Foundation for Innovation and the Ministry of Research and Innovation's Ontario Research Fund, provided the infrastructure for the conduct of this project. Ms McGlynn was supported by a CIHR-Masters Award and a Research Training Centre scholarship from St Michel's Hospital. Dr Comelli was funded from holding the Lawson Family Chair in Microbiome Nutrition Research at the University of Toronto. Dr Salas-Salvadó was funded by the ICREA (Catalan Institution for Research and Advanced Studies) Academia program. Dr Sievenpiper was funded by a PSI Graham Farquharson Knowledge Translation Fellowship, Diabetes Canada Clinician Scientist Award, CIHR INMD/CNS New Investigator Partnership Prize, and a Banting & Best Diabetes Centre Sun Life Financial New Investigator Award.

Role of the Funder/Sponsor: The Clinical Practice Guidelines Committee of the DNSG of the EASD had input on all aspects of this work. Other funders had no role in the design and conduct of the study; collection, management, analysis, and interpretation of the data; preparation, review, or approval of the manuscript; and decision to submit the manuscript for publication.
